

In this homework, I set the matrix A:

$$\begin{matrix} 2 & 3 \end{matrix}$$

$$\begin{matrix} 1 & 2 \end{matrix}$$

$$\begin{matrix} 3 & 4 \end{matrix}$$

b:

$$\begin{matrix} 1 \end{matrix}$$

$$\begin{matrix} 2 \end{matrix}$$

$$\begin{matrix} 3 \end{matrix}$$

P1:

$$\begin{matrix} 1 & 1 \end{matrix}$$

$$\begin{matrix} 1 & 3 \end{matrix}$$

P2:

$$\begin{matrix} 2 & 0 \end{matrix}$$

$$\begin{matrix} 0 & 1 \end{matrix}$$

P3:

$$\begin{matrix} 2 & 1 \end{matrix}$$

$$\begin{matrix} 1 & 2 \end{matrix}$$

$\epsilon = 1$ and $\kappa = 0.2$.

To decide μ and L , I take the second derivative both objective function and constraint function.

For f_0 , the second derivative is: $2A^T A$. For f_1 to f_3 , the second derivative is $2P_i^{-1}$. After computing,

I choose the minimum of the above as μ and the maximum as L for our problem.

Then I set the function f_0 , f_1 , f_2 and f_3 and used the “diff” function to calculate their derivative

expression.

Before the loop, I set initial t as -100.

In each inner loop, I first check if $f^*(t; x_k; \mu)$ is larger than $(1-\kappa) f^*(t; x_k; L)$, calculating with Optimization tool “fmincon()”. If it is larger, then the condition breaks the inner loop and begins to update the t value. Or the inner loop would keep generating a sequence of x_k until it meets the requirements. With the valid x_k sequence, we find the x_k with minimum $f^*(t; x_k; L)$. This x_k would be our initial point in the next iteration of exterior loop.

In the exterior loop, I use the bidirectional search to find the next t : first check if the current $f^*(t; x_k; \mu)$, where x_k is the last of the inner loop sequence, is between the value when $t = -100$ (lower boundary) and when $t = \text{norm}(b)$ (upper boundary). Then we set

$t = (\text{lower boundary} + \text{upper boundary}) / 2$ and check the $f^*(t; x_k; \mu)$ with the new t . if it is larger than zero, the new t becomes the lower boundary. If it is smaller than zero, the new t becomes the upper boundary. As the lower boundary and upper boundary merge together, I can get a t that can make $f^*(t; x_k; \mu)$ as 0 approximately.

In each inner loop iteration, I check if $f^*(t; x_k; L) \leq \varepsilon$. If it meets the requirement, the inner loop will save the current x and jump out both inner loop and exterior loop.

The program runs relatively fast (3 seconds). The final result I get is $x = [0.6363; 0.2126]$.
